

BOATBUILDER'S HANDBOOK

[REVISED NOVEMBER, 2003]

*Produced Under A Grant From
The Aquatic Resources (Wallop-Breaux) Trust Fund
Administered By The U.S. Coast Guard.*

SUBPART I

ELECTRICAL SYSTEMS

Revised November, 2003

Title 33 CFR, Sections 183.401–183.460

WARNING:

This guide only addresses provisions of the Federal Regulations.
It is NOT a complete engineering manual for the design of boat systems.
It is the manufacturer's responsibility to ensure Federal Regulations
cited in this guide have not been updated or revised.

Introduction

Electrical systems for many types of boats are complex. U. S. Federal regulations address critical areas pertaining to electrical systems from the standpoint of safety and stipulate requirements to assure good practice in these areas. Some requirements may be specifically applied but many requirements interact with others such as determination of wire size and overcurrent protection. The large number of requirements and the possible interpretations tend to be confusing for those using the regulations.

Regulations are typically written in concise terms, the words and arrangement chosen to be enforceable and in some cases to be legally interpreted. This format prohibits including explanations, recommendations and easily detected alternate solutions. A regulation provides an outline about which a great deal of further information, interpretation, explanation, clarification and helpful hints are needed in order to provide good understanding and compliance with its intent.

This electrical system guideline attempts to assist the average boat builder in achieving compliance with these regulations. It explains, diagrams, makes some recommendations and, in general, complements the regulations to improve the boat builder's understanding.

CAUTION:

This guideline only addresses provisions of the Federal Regulations. It is not a complete engineering manual for the design of electrical systems on boats. There are other manuals and standards available for this purpose such as American Boat & Yacht Council (ABYC) standards E-2, E-4, E-8, E-9 and E-10.

FORMAT

The format of this guideline has been chosen to follow the sequence in the electrical system regulation. This format provides a consistent sequence of information, thereby reducing confusion for the boat builders and component manufacturers who use it.

A portion of a regulation, titled FEDERAL LAW, is stated and then a discussion follows. The discussion explains, interprets, clarifies, identifies interdependence of requirements, and is designed to improve the understanding of the intent of the regulatory requirement. Diagrams are freely used, and tables included wherever they can be helpful.

The discussion, diagrams and tables are followed by compliance information identified by the title TO COMPLY WITH THE LAW, that asks questions to which the answer must be "yes" if compliance is to be achieved. This is a checklist for each regulatory requirement. There are further questions covering other factors and situations which should be considered.

Typical electrical systems of various types of boats are annotated to show the applicable section of the regulation. The systems shown are examples and are not intended to be limiting in any way. Both simpler and more complex systems may be installed on any of the depicted boats. The appendix lists references and resources.

General

FEDERAL LAW:

183.401 Purpose and applicability.

- (a) This subpart applies to all boats that have gasoline engines, except outboard engines, for electrical generation, mechanical power, or propulsion.

Figure 1 Applicability

NOTE:

Boats powered with outboard engine(s) are not subject to these regulations unless there is also a gasoline powered engine installed on the boat such as a gasoline powered auxiliary generator. The outboard motor and its associated control wiring are excepted. Associated control wiring includes power cables, ignition wires, gauge wires, etc. A battery used only for the trolling motor becomes part of its associated control wiring and is therefore not subject to the regulation's requirements, including the battery securing and restraint requirements of 183.420.

FEDERAL LAW:

183.402 **Definitions.**
 As used in this subpart:

(a) AWG means American Wire Gauge.

The gauge of a wire is its size. The American Wire Gauge is a nationally accepted convention for designating wire sizes. The higher the number, the smaller the diameter of the wire. For example, 16 gauge wire has a smaller diameter than 12 gauge wire. For large sizes of wire, 0, 00, 000 and 0000 are used. The more zeros, the larger the wire.

FIGURE 2 **Conductor Gauge (insulation not included)**

(APPROXIMATE SIZES – FOR COMPARISON ONLY)

Conductors may be labeled with their size. If not, and the size is to be determined, then measure the diameter of an individual strand using a micrometer. Square the diameter of the strand (in mils) and multiply by the number of strands in the conductor. This will provide the total circular-mil area of the conductor. Refer to Table 1 to find the gauge.

TABLE 1 **Conductors**

Conductor Size	MINIMUM ACCEPTABLE CM AREA SAE (See Note 2)	MINIMUM ACCEPTABLE CM AREA AWG (See Note 3)	APPROXIMATE DIAMETER OF WIRE—INCHES (Insulation not included)
18	1,537	1,620	.050
16	2,336	2,580	.060
14	3,702	4,110	.075
12	5,833	6,530	.090
10	9,343	10,380	.115
8	14,810	16,510	.160
6	24,538	26,240	.210
4	37,360	41,740	.275
2	62,450	66,360	.335
1	77,790	83,690	.375
0	98,980	105,600	.420
00	125,100	133,100	.475
000	158,600	167,800	.535
0000	205,500	211,600	.595

Formula: $CM = d^2 \times N$

Where: d = diameter of one strand in mils (one mil = .001 inch)
N = number of strands in the conductor

NOTE:

1. If the conductor contains strands of various sizes, measure the diameter of each strand, square the diameter, and add the individual circular mil area for the conductor.
2. Below 50 volts, SAE wire size may be used.
3. 50 Volts and above, AWG wire size **MUST** be used.

FEDERAL LAW:

183.402 Definitions.
As used in this subpart:

- (b) Electrical component means electrical equipment such as but not limited to, conductors, solenoids, motors, generators, alternators, distributors, resistors, appliances and electrical control devices.

In general, any item related to the electrical system is an electrical component. A panel box is NOT itself an electrical component, but it contains a number of electrical components. Support clamps and straps and their fastenings are NOT electrical components.

It must be noted that the regulation's requirements apply to the installation of electrical components, and their external connection into the electrical circuit. The regulation does not apply to internal wiring or terminations within a component. For example, the windings of a motor, generator or alternator are not regulated; however, the external wiring used to connect them to a boat's electrical system is required to comply with the regulation. The construction details of electrical components are only regulated insofar as whether the electrical component is or is not ignition protected.

FEDERAL LAW:

183.402 Definitions.
As used in this subpart:

- (c) **Pigtails means external power conductors or wires that are part of electrical components and appliances, such as bilge pumps, blowers, lamps, switches, solenoids, and fuses.**

Pigtails are the wires that are provided by a device manufacturer to connect the device into the electrical circuit. Pigtails are usually electrically connected internally and led through a protective covering to be connected to electrical service connectors. Examples of electrical devices that are commonly equipped with pigtails are cabin lighting fixtures, navigation light fixtures, blowers, bilge pumps, horns, searchlights, indicator lights, in-line fuses, switches and solenoids.

The regulation exempts pigtails that are less than 7 inches in length, only from:

- 183.425 — Conductors: General
- 183.430 — Conductors in Circuits of Less Than 50 Volts
- 183.435 — Conductors in Circuits of 50 Volts or More
- 183.455 — Overcurrent Protection: General

To determine the length of pigtails, measure the length of conductors that are visible outside the device, i.e. from the point on an electrical component where the conductors pass through a shell or housing to their end. This length must be less than 7 inches if the pigtails are to be excepted from these requirements. The portions of the conductors inside the component are not part of this pigtail length. In bilge installations, the pigtail connections must not be below the level of normal bilge water accumulation.

FEDERAL LAW:

183.402 **Definitions.**
As used in this subpart:

- (d) **Sheath means a material used as a continuous protective covering, such as electrical tape, molded rubber, molded plastic, or flexible tubing, around one or more insulated conductors.**

A “sheath” is a flexible continuous covering, as distinguished from a “conduit” or “duct” which are rigid continuous coverings. As the regulation states, a “sheath” may be a continuous wrapping of electrical tape, molded or extruded rubber or plastic, or flexible tubing (sometimes referred to as “spaghetti”).

A “sheath” may be used around one or a number of conductors, which may or may not be different gauges. Each of the conductors must be insulated, that is, the sheath is NOT to take the place of a conductor’s insulation.

A “sheath” does not have to hold the conductors tightly bonded together. Individual conductors are allowed to move in relation to each other within a sheath. A “sheath” is generally used as a means of grouping conductors to maintain a neat appearance as the conductors are run through the boat.

FEDERAL LAW:**183.405 General.**

Each electrical component on a boat to which this subpart applies must meet the requirements of this subpart unless the component is part of an outboard engine or part of portable equipment.

The equipment standards of this regulation appear to impose requirements, and consequently certification responsibilities on component manufacturers. This is not the case. The boat manufacturer is the responsible party under these regulations and he must certify compliance.

What does certification mean? Certification means to test and verify that the boat complies with the law.

The boat manufacturer is required to certify that the boat complies with this standard, not the equipment manufacturers of each component. Component parts of outboard engines and portable equipment, such as a self-contained engine-generator unit, are not covered by these regulations.

Purchase orders can stipulate that component manufacturers assure compliance, which a boat manufacturer may choose to recognize as supporting evidence in certifying the entire electrical system. Recognized, acceptable marine listings or labels may be used as supporting evidence of compliance. This does not, however, relieve the boat manufacturer of certification responsibility.

FEDERAL LAW:**183.410 Ignition Protection.**

- (a) Each electrical component must not ignite a propane gas and air mixture that is 4.25 to 5.25 percent propane gas by volume surrounding the electrical component when it is operated at each of its manufacturer rated voltages and current loadings, unless it is isolated from gasoline fuel sources, such as engines, and valves, connections, or other fittings in vent lines, fill lines, distribution lines or on fuel tanks, in accordance with paragraph (b) of this section.

An electrical component that is “ignition protected” is capable of operating in an explosive environment without igniting that environment. “Ignition protection” of electrical devices is accomplished by the use of seals, flame arrestors and potting (sealing), or a combination of such means.

An “ignition protected” component:

- will not ignite a flammable hydrocarbon mixture surrounding the device when an ignition source causes an internal explosion, or;
- is incapable of releasing sufficient electrical or thermal energy to ignite a hydrocarbon mixture; or
- has the source of ignition hermetically sealed.

A flammable hydrocarbon mixture is a mixture of gasoline and air, or propane and air, between the lower explosive limit (LEL) and the upper explosive limit (UEL).

In general, the tests are conducted in an explosion chamber containing an explosive atmosphere, defined by this regulation as a 4.25 (LEL) to 5.25 (UEL) percent mixture by volume of propane gas and air. The mixture is introduced into the component where internal sparking occurs, or is induced, so that an explosion is evident within the component. An internal explosion must not ignite the explosive atmosphere surrounding the device in order for the component to pass the test. To assure compliance of a component, this sequence is repeated 50 times. Propane, not gasoline, is used for ignition protection tests because it is much easier to get repeatable results using this mixture rather than gasoline vapor.

NOTES:

1. *It is not the intention to require such devices to be "explosion proof" as that term is defined in the National Electrical Code of the National Fire Protection Association pertaining to shore systems, or within the meaning of 46 CFR 110.15-65.(e), Subchapter J, "Electrical Engineering". It is intended that the protection provided be generally equivalent to that of wiring permitted by this standard wherein a definite short or break would be necessary to produce an open spark.*
2. *Devices that are "explosion proof " are considered to be "ignition protected" when installed with the appropriate fittings to maintain their "explosion proof" integrity.*

To determine if a component is "ignition protected", there are a number of test procedures available that are acceptable to the U.S. Coast Guard. For details of these test procedures, refer to the following:

- SAE J1171 "External Ignition Protection of Marine Electrical Devices"
- UL 1500 "Standard Test Procedure for Ignition Protection"
- USCG "USCG Compliance Test Procedure — Electrical System Standard"
Published January, 1973. Re-print available through ABYC.

TO COMPLY WITH THE LAW

- *Is each electrical component which is not isolated from gasoline fuel sources "ignition protected"?*

FEDERAL LAW:**183.410 Ignition Protection.**

(b) An electrical component is isolated from a gasoline fuel source if:

- (1) A bulkhead that meets the requirements of paragraph (c) of this section is between the electrical component and the gasoline fuel source;

The regulation also provides an alternative where electrical components need not be ignition protected. If the electrical component is installed in a boat and is isolated from gasoline engines and gasoline fuel system components, except for uninterrupted runs of fuel lines, then the electrical component does not need to be ignition protected. Isolation of electrical components is discussed in 183.410 (b)(2), later in this guideline.

Isolation of an electrical component may be accomplished in a number of ways:

1. Bulkheads.
2. Deck or special enclosures.
3. Installing the component in an open space with 2 feet minimum distance from the source of fuel.

This section deals with bulkheads; the next two sections discuss the other methods.

A bulkhead is a vertical wall-like structure that may run transversely (across) or longitudinally (fore to aft) in a boat. Bulkheads are used both for strength and to separate a boat into different use areas, such as engine room, fuel tank compartment, living space, storage compartment, etc. By taking advantage of the location of bulkheads and installing electrical components accordingly, it may be possible to use non-ignition protected electrical components in many installations. Figures 3, 4, 5 and 6 depict some typical boats and the use of bulkheads for isolation.

A bulkhead and deck may be combined to accomplish isolation, such as where a boat has a cabin bulkhead in front of the engine compartment and a deck over the engine compartment.

Specific details of the construction of a bulkhead including watertightness, opening, penetrations and structural extent are covered in 183.410.(c), later in this guideline.

TO COMPLY WITH THE LAW

- *Is each electrical component either isolated by a bulkhead or ignition protected?*

FEDERAL LAW:**183.410 Ignition Protection.**

(b) An electrical component is isolated from a gasoline fuel source if:

(2) The electrical component is:

- (i) Lower than the gasoline fuel source and a means is provided to prevent fuel and fuel vapors that may leak from the gasoline fuel source from becoming exposed to the electrical component; or
- (ii) Higher than the gasoline fuel source and a deck or other enclosure is between it and the gasoline fuel source; or

This section deals with how to use decks or special enclosures to achieve isolation of electrical components. The previous section discussed bulkheads; the next section discusses open spaces and minimum distances.

Isolation that separates an electrical component from a gasoline fuel source may be accomplished by a deck between the two or by means of an enclosure. Either the electrical component or the gasoline fuel source may be enclosed to accomplish isolation.

The electrical component may be installed lower or higher than the gasoline fuel source.

If the electrical component is installed lower than the gasoline fuel source, then the deck or enclosure used to create the isolation must prevent liquid fuel and fuel vapors from coming in contact with the electrical component. This requires the compartment to be liquid (water) tight and vapor tight.

If the electrical component is installed higher than the gasoline fuel source, then there must be a deck or enclosure to create the isolation, but it is not necessary that it be liquid or vapor tight. Fuel vapors are heavier than air and would tend to collect below the isolation deck or enclosure. Should it be obvious in a specific installation that fuel vapors could surround an electrical component, then good practice would be to make the deck or enclosure an isolation barrier or to select ignition protected electrical components.

Figures 3, 4, 5, 6, and 7 depict typical boats and the use of decks and enclosures for isolation.

TO COMPLY WITH THE LAW

- *Is each electrical component either isolated or ignition protected?*

FEDERAL LAW:**183.410 Ignition Protection.**

- (b) An electrical component is isolated from a gasoline fuel source if:
- (3) The space between the electrical component and the gasoline fuel source is at least two feet and the space is open to the atmosphere.

This section deals with isolation of an electrical component using open spaces and minimum distances. The previous two sections discussed bulkheads, and decks or special enclosures, respectively.

Ignition protection is not required for electrical components that are in a space that is open to the atmosphere and is located at least two feet from a gasoline fuel source. The term "open to the atmosphere" is defined as a space or a compartment having at least 15 square inches of unobstructed area opening into the compartment for every square foot of compartment volume. Open boats, such as runabouts, with the engine aft and the fuel tank located far enough forward to meet the two foot provision will be able to use non-ignition protected components in their instrument panel. Figure 8 depicts a typical open boat, whose bow compartment is open to the atmosphere, with a two foot distance maintained between electrical components and the gasoline fuel source. Figure 4 shows a saddle tank installation with a two foot distance between electrical components and the gasoline fuel source.

TO COMPLY WITH THE LAW

- *Is each electrical component either isolated or ignition protected?*

FIGURE 3 Isolation of Electrical Components

FIGURE 4 Isolation of Electrical Components

FIGURE 5 Isolation of Electrical Components**FIGURE 6** Isolation of Electrical Components

FIGURE 7 Isolation of Electrical Components

Partial Bulkhead — Foot board, Toe board — In figure 8a,b,c, we see how boat structures such as a partial bulkhead may be fitted to increase the distance between the source of fuel and the source of ignition.

FIGURE 8a Isolation of Electrical Components

POTENTIAL IGNITION SOURCE WITHIN 2' OF FUEL SOURCE MUST BE IGNITION PROTECTED.

In figure 8a, the switches in the dashboard are within 2' of the fuel deck fitting, and also within 2' of the fitting at the fuel tank. Each of these fittings is a potential source of fuel leak. In this installation, all switches would have to be ignition protected.

FIGURE 8b Isolation of Electrical Components

Here the builder has fitted a partial bulkhead across the boat, behind the dash to increase the distance between the fuel deck fitting and the backside of the dash. The builder has also decked over the front of the tank so that the tank fitting is also more than 2' from the back of the dash.

FIGURE 8c Isolation of Electrical Components

Here there are three potential sources of fuel: The vent fitting in the side of the hull, the fuel deck fitting, and the connections at the tank. The vent and fill fittings are more than 2' from the dashboard. The tank fittings were too close to the dashboard. Here the boat builder has installed a foot board to increase the separation from the dashboard.

FEDERAL LAW:**183.410 Ignition Protection.**

(c) Each bulkhead required by paragraph (b)(1) of this section must:

- (1) Separate the electrical component from the gasoline fuel source and extend both vertically and horizontally the distance of the open space between the fuel source and the ignition source;
- (2) Resist a water level that is 12 inches high or one-third of the maximum height of the bulkhead, whichever is less, without seepage of more than one-quarter fluid ounce of fresh water per hour; and
- (3) Have no opening located higher than 12 inches or one-third the maximum height of the bulkhead, whichever is less, unless the opening is used for the passage of conductors, piping, ventilation ducts, mechanical equipment, and similar items, or doors, hatches, and access panels, and the maximum annular space around each item or door, hatch or access panel must not be more than one-quarter inch.

To effectively separate a gasoline fuel source and an electrical component by a bulkhead, the regulation has established certain criteria covering the following:

- the extent of the bulkhead both horizontally and vertically.
- the water-resistant height of the bulkhead and permitted rate of seepage.
- openings through the bulkhead below the water-resistant height.
- openings through the bulkhead above the water-resistant height.

Figures 9 and 10 depict a typical bulkhead installation with a number of the regulated items noted.

Bulkhead Extent — A bulkhead intended to isolate an electrical component from a gasoline fuel source must effectively close off one space from another. The bulkhead must be fitted closely to the sides, bottom and top of the space or compartment. There should be no vent holes, corners snipped off, limber holes or hand holds in this bulkhead. It should reach the full width and the full height of the space being closed off.

Water-Resistant Height — The water-resistant height to be used for a particular bulkhead is based on the maximum height of the bulkhead. The water-resistant height is the lesser of 12 inches or one-third the maximum height of the bulkhead. For example, if the total height from the lowest point of the bulkhead to the uppermost point of the bulkhead is 33 inches, then the water-resistant height is 11 inches. If the total height is 42 inches, then the water-resistant height is 12 inches (less than one-third of 42 inches). Any openings for piping, wiring, ducting, controls, etc. must have a sealed fitting used to prevent seepage around the item going through the bulkhead. The total maximum seepage permitted for the entire area of the bulkhead below the water-resistant height is one-quarter ounce (approximately one-half tablespoon) of fresh water per hour.

Openings Below the Water-Resistant Height — Bulkheads used for isolation may have openings for: wiring, piping, ducts, controls, doors, hatches, access panels, drains, and other such purposes, but each opening located below the water-resistant height of the bulkhead must be sealed or have a fitting to minimize seepage. Doors and hatches or portions thereof must also be fitted or sealed to minimize seepage. The maximum seepage permitted for all openings and edges of the bulkhead may not exceed a total of one-quarter ounce (approximately one-half tablespoon) of fresh water per hour.

Openings Above the Water-Resistant Height — Openings above the water-resistant height are permitted for: wiring, piping, ducts, controls, doors, hatches, access panels, drains, and other such purposes, but each opening must not have more than a one-quarter inch wide space around whatever passes through the bulkhead, such as piping, wiring, ducts, controls, etc. Hatches, doors, access panels, etc. must be fitted so there is no more than one-quarter inch clearance around them when they are closed, except if they extend below the water-resistant height (see above), where they must be sealed.

Openings for wiring, piping, etc. in the bulkheads surrounding the engine and exhaust components may also allow carbon monoxide to enter the accommodation spaces of the boat. Extra attention is recommended to seal those openings to reduce the passage of carbon monoxide gas.

SPECIAL NOTE:

The U.S. Coast Guard has developed the following compliance policy concerning drain holes in isolation bulkheads:

“Any hole installed for drainage in an isolation bulkhead must be fitted with a plug or sealing device that is intended to be in place when the boat is being used. The plug or sealing device must be attached to the drain fitting or the bulkhead near the drain hole so it will not be lost. It must be understood that when this drain hole is open, the isolation integrity of the bulkhead has been breached causing a potentially hazardous condition. It is the responsibility of the boat manufacturer to make this intent known to the consumer via means such as labeling, information in a boat owners manual, etc.”

TO COMPLY WITH THE LAW

Is each bulkhead used for isolation —

- (1) between the gasoline fuel source and the electrical component?*
- (2) extended to a full width and height?*
- (3) water-resistant, except for permitted seepage, to the lesser height of 12 inches or one-third the maximum height of the bulkhead?*

Is the annular space around hatches, doors, access panels, etc. or items passing through the bulkhead and located above the water-resistant height of the bulkhead not more than 1/4 inch?

FIGURE 9 Isolation Bulkhead Requirements

FIGURE 10 Bulkheads**NOTES TO FIGURE 10:**

1. Seepage of not more than one-quarter fluid ounce per hour permitted below the water-resistant height. This includes bulkhead fastenings and around any openings.
2. Openings above the water-resistant height may not have more than 1/4 inch annular space around the opening.

FEDERAL LAW:**183.415 Grounding.**

If a boat has more than one gasoline engine, grounded cranking motor circuits must be connected to each other by a common conductor circuit that can carry the starting current of each of the grounded cranking motor circuits.

The purpose of this requirement is to prevent accidental passage of the battery supply current through fuel systems and smaller electrical conductors that may be common to engines. If one of the grounded cranking motor circuits accidentally opens (breaks) due to corrosion, vibration, etc., the accidental passage of starter motor current could melt fuel lines or burn up smaller conductors such as instrument wiring. Both of these hazards could lead to fire and explosion accidents. The common conductor circuit referred to in the regulation is a circuit made up of jumper conductors and may include a common bus bar.

Definitions:

Ground — ground applies to the potential of the earth's surface. The boat's ground is established by a conducting connection (intentional or accidental) with the earth, including any conductive part of the wetted surface of a hull.

Grounded Conductor — a current-carrying conductor connected to the side of a source which is intentionally maintained at boat ground potential.

In a two engine installation, a jumper conductor will satisfy compliance if connected between the negative sides of the grounded cranking motor circuit.

In installations of three or more grounded cranking motor circuits, the common conductor circuit can be of several different configurations. Installing a common bus bar to which a conductor from each circuit is attached is one approach.

Common and convenient points of attachment to the negative side of the grounded cranking motor circuits are the engine negative terminal, any point on the engine block, and in direct contact with the negative side of the cranking motor.

In all cases, proper sizing of the conductor leading from each grounded cranking motor circuit is imperative. A rule of thumb to use when selecting the conductor is to use one as large as the conductor used to supply power from the battery to the cranking motor (the battery cable). Table 5 of the regulation can also be used as a guide when selecting the conductor.

If there are two or more starting battery installations and the negative terminals are connected by a common conductor, that common conductor does not satisfy this grounding requirement. Additional conductor(s) are necessary. Figure 11 diagrams typical circuits.

FIGURE 11 Cranking Motor Circuits**TO COMPLY WITH THE LAW**

If there is more than one grounded cranking motor circuit:

- *Are the grounded cranking motor circuits connected by a common conductor circuit?*
- *Is the common conductor circuit properly sized to carry the starting current of each of the grounded cranking motor circuits?*

FEDERAL LAW:**183.420 Batteries.**

- (a) Each installed battery must not move more than one inch in any direction when a pulling force of 90 pounds or twice the battery weight, whichever is less, is applied through the center of gravity of the battery as follows:
 - (1) Vertically for a duration of one minute.
 - (2) Horizontally and parallel to the boat's center line for a duration of one minute fore and one minute aft.
 - (3) Horizontally and perpendicular to the boat's center line for a duration of one minute to starboard and one minute to port.

If a battery was allowed to reposition itself indiscriminately at the will of the forces that occur when a vessel (especially smaller boats with quicker motion) is operated in waves, or while being transported over land with its battery installed, the battery could become damaged. If the battery casing ruptures, the electrolyte may run out. If a battery terminal loosens, poor contact or sparking could occur. The electrolyte is usually sulfuric acid which can severely attack many metals and other materials. Such attack on fuel system components has the potential of causing fuel lines and fittings to fail and leak fuel. Movement of a battery could cause the battery terminal to come in contact with grounded items, resulting in sparking.

Therefore, the regulation calls for restraint of the battery in the horizontal and vertical directions. A battery as installed by a manufacturer may not move more than one inch when subjected to a test force for a one minute duration in each of three directions: vertical, horizontal — fore and aft, and horizontal — port and starboard. The test force selected is 90 pounds, which is approximately twice the weight of the popular size of marine battery used in small boats, which may be subject to high accelerations. For this reason, 90 pounds was selected as the maximum that needed to be applied. For batteries weighing less than 45 pounds, a force of twice the battery weight is specified. This test force is to be applied through the center of gravity of the battery. (See Figure 12).

The commercially available plastic battery boxes may be used to install a battery; however, it may be necessary to provide means within the battery box to prevent excess movement of the battery. The materials used for restraining battery movement within a battery box should be selected with regard to potential deterioration by the electrolyte. The battery box must be fastened in such a manner that the battery installation will comply with this section of the regulation.

It is recommended that the use of materials to wedge the battery in a battery box be described in the boat's owners manual to affirm its intended use. (See Figure 13).

TO COMPLY WITH THE LAW

Is the battery installed so that it will not move more than 1 inch in any direction when a force of 90 pounds or twice the battery's weight, whichever is less, is applied for one minute each:

- *Vertically?*
- *Horizontally — Forward?*

FIGURE 13 Installation in a Battery Box

FEDERAL LAW:**183.420 Batteries.**

- (b) Each battery must be installed so that metallic objects cannot come in contact with the ungrounded battery terminals.

If an ungrounded battery terminal is left exposed, it is possible that an accidental connection to ground could occur. The use of, or dropping of, tools nearby could make such a connection during routine engine servicing. This connection could result in a spark of sufficient energy to ignite any explosive vapors that might be present or to start an electrical fire.

To prevent accidental contact with the ungrounded battery terminal, it may be covered with a boot or non-conductive shield. The battery could be installed in a covered battery box or special, fitted compartment. (See Figure 14).

TO COMPLY WITH THE LAW

- *Have precautions been taken to prevent metallic objects from coming in contact with the ungrounded battery terminal when the battery is in its installed position?*

FIGURE 14 Ungrounded Battery Terminal Connection

FEDERAL LAW:**183.420 Batteries.**

- (c) Each metallic fuel line and fuel system component within 12 inches and above the horizontal plane of the battery top surface as installed must be shielded with dielectric material.

Metallic fuel lines and fuel system components are usually electrically grounded, either intentionally or because they are connected to an engine or a fuel tank. If, while servicing, installing or removing the battery, a tool should contact the ungrounded (positive) terminal and the fuel line or component, a spark could occur. This could cause the battery to explode, or a hole could be burned in the fuel line, creating a fire or fuel explosion hazard. Also, installing or removing a battery with exposed terminals could result in both terminals contacting a fuel line or component, which could result in a similar hazard.

The regulation calls for shielding of fuel lines and components within 12 inches of the top surface of the battery. Twelve inches was chosen as a practical distance to provide for installation or removal of a battery. Terminal insulation or battery covers are not considered adequate since these protective devices are usually removed during installation or removal of a battery.

Figure 15 shows the envelope within which any fuel line or fuel system component must be shielded, using a dielectric material. Any non-conductive material may be used for shielding as long as it is durable enough to withstand accidental contact by a tool or the battery terminals during servicing, installation or removal. Some materials that appear suitable include electrical tape (continuous wrapping), plastic pipe or tubing, dielectric sheathing, fiberglass, wood, etc.

TO COMPLY WITH THE LAW

- *Is each metallic fuel line and fuel system component, within the envelope shown in Figure 15, dielectrically shielded?*

FIGURE 15 Dielectric Shielding Envelope

FEDERAL LAW:**183.420 Batteries.**

(d) Each battery must not be directly above or below a fuel tank, fuel filter, or fitting in a fuel line.

Certain components of the fuel system have been identified as prime sources of potential leakage. These items are the fuel tanks, fuel filters, and fuel line fittings. Many fuel filters are equipped with drain plugs for servicing.

If a battery is installed directly below these fuel components, there is a potential for gasoline to leak on the battery, possibly attacking the battery case material.

If a battery is installed directly above the fuel items, leaking electrolyte may attack fuel system components, creating fuel leakage. (See Figure 16).

Also of concern is the servicing of fuel system components if a battery is installed directly above or below them. Accidental short circuiting may occur while servicing, installing or removing a battery.

This does not prohibit a battery from being installed directly above or below an uninterrupted fuel line; however, if a metal fuel line is within the 12 inch envelope of the top surface of the battery, it must be shielded dielectrically as required in 183.420(c).

TO COMPLY WITH THE LAW

Is each battery installed away from:

- *Directly above a fuel tank, fuel filter and fuel line fittings?*
- *Directly below a fuel tank, fuel filter and fuel line fittings?*

FEDERAL LAW:**183.420 Batteries.**

(e) A vent system or other means must be provided to permit the discharge from the boat of hydrogen gas released by the battery.

Hydrogen gas is very explosive. Boat design and battery installations that permit the accumulation of hydrogen gas must be avoided since batteries emit hydrogen gas. Even “sealed” batteries have venting provisions and therefore must be considered vented batteries.

Hydrogen gas will disperse rapidly and will seek to exit through any opening, particularly through overhead openings, since the gas is lighter than air. Pockets above the battery that could trap and hold the hydrogen gas must be vented. Likewise, a battery box whose cover forms a pocket over the battery must be vented.

Particular attention must be paid to battery installations in special, isolated compartments that are not part of ventilated compartments. These areas may require special ventilation considerations to accommodate battery installations.

If in doubt about gas accumulation in the boat, a test may be conducted by charging the battery in the boat. The boat should be equipped as it would be in normal service, particularly in terms of normally supplied means of ventilation. A gas analyzer may be used to check areas above the battery where hydrogen gas accumulation is possible. If there are no dangerous quantities of gas found, then the installation should be acceptable.

The best practice is to install batteries in well ventilated locations.

TO COMPLY WITH THE LAW

- *Is hydrogen gas allowed to escape the storage location and the boat?*

FEDERAL LAW:**183.420 Batteries.**

(g) Each battery terminal connector must not depend on spring tension for its mechanical connection to the terminal.

The integrity of the battery terminal connections is very important to prevent sparking and overheating of the terminal. Failures of a battery terminal connection could result in a fire and explosion hazard.

By prohibiting spring-type battery terminal connectors, the regulation requires the use of mechanical connections that are not likely to loosen due to vibration.

There are two types of battery terminal connections in prevalent use. They are the clamp type, and the bolt-on type. Figure 17 depicts these types, as well as a spring-type which is PROHIBITED.

TO COMPLY WITH THE LAW

- *Is each battery terminal connector provided with a mechanical terminal connection that does NOT depend on spring tension?*

FIGURE 17 Battery Terminal Connections

FEDERAL LAW:**183.425 Conductors: General.**

(a) Each conductor must be insulated, stranded copper.

Each conductor must be insulated with an insulation compound meeting:

- Sec. 183.430, if less than 50 volts, or
- Sec. 183.435, if 50 volts or more.

The conductor must be stranded to resist failure due to vibration and flexing. Copper is specified for the best combination of conductivity and corrosion resistance.

TO COMPLY WITH THE LAW

- *The conductor insulation material conforms to either 183.430 or 183.435 depending on the voltage application (less than 50 volts, or 50 volts or more).*
- *The construction is of stranded copper (note permitted exceptions in 183.425(g)).*

FIGURE 18 Insulated Stranded Copper Conductor

FEDERAL LAW:**183.425 Conductors: General.**

- (b) Except for intermittent surges each conductor must not carry a current greater than that specified in Table 5 for the conductor's gauge and temperature rating.
- (c) For conductors in engine spaces, amperages must be corrected by the appropriate correction factor in note 1 of Table 5.

The current values referred to in Table 5 are constant or steady values as compared with the intermittent higher currents which may occur momentarily in circuits, such as those associated with stern-drive trimming devices or electrical motor starting situations. To select a conductor size use the maximum steady state load.

Due to engine heat, the ambient temperature in engine spaces is usually higher than in other spaces of the boat. Wiring in and passing through engine spaces must be able to operate at these higher ambient temperatures. The ampacity values in Table 5 are based on an ambient temperature of 30° C (86° F), which is considered reasonable for use on boats except in engine spaces. The correction factors of Note 1 in Table 5 convert the ampacities of Table 5 to acceptable values in an ambient temperature of 50° C (122° F). This higher temperature has been selected as satisfactory for engine spaces.

Tables 5A through 5E are supplied to eliminate the need for calculating the corrections to Table 5 (see Notes 1 and 2 under Table 5). The values are already corrected. Sample calculations appear under the discussion of section 183.435 (a) later in this guideline.

TO COMPLY WITH THE LAW

- *Conductor gauge and temperature ratings are selected to carry current equal to, or less than, the values given in Table 5 (and associated Tables 5A through 5E).*

FEDERAL LAW:

183.425 Conductors: General.

- (d) Each conductor in a multiconductor sheath must be at least a No. 18 AWG conductor.
- (e) Each conductor installed separately must be at least a No. 16 AWG conductor.
- (f) Each No. 18 AWG conductor in a multiconductor sheath may not extend out of the sheath more than 30 inches.

A conductor smaller than 16 AWG may not be used by itself. An 18 AWG is the smallest conductor permitted, except for the regulatory exceptions, and it must be in a multiconductor (2 or more conductors) sheath.

An 18 AWG conductor is limited to a 30 inch length from the end of a sheath. (See Figure 19).

NOTE:

SAE conductor sizes are acceptable in place of AWG.

FEDERAL LAW:

183.425 Conductors: General.

- (g) This section does not apply to communication systems; electronic navigation equipment; electronic circuits having current flow of less than one ampere; conductors which are totally inside an equipment housing; resistance conductors that control circuit amperage; high voltage secondary conductors and terminations that are in ignition systems; pigtails of less than seven inches of exposed length; and cranking motor conductors.

TO COMPLY WITH THE LAW

- *No conductor smaller than No. 16 AWG is used separately.*
- *Any No. 18 AWG conductor used is protected in a suitable multiconductor sheath and does not extend out of this sheath more than 30 inches.*

NOTE PERMITTED EXCEPTIONS in 183.425 (g)

FIGURE 19 Permitted Conductor Size

FEDERAL LAW:**183.430 Conductors in Circuits of Less Than 50 Volts.**

- (a) Each conductor in a circuit that has a nominal voltage of less than 50 volts must:
 - (1) Meet the requirements of 183.435; or
 - (2) Meet:
 - (i) The insulating material temperature rating requirements of SAE Standard J378; and
 - (ii) SAE Standard J1127 or SAE Standard 1128.
- (b) This section does not apply to communication systems; electronic navigation equipment, resistance conductors that control circuit amperage; and pigtails of less than seven inches of exposed length.

This section allows alternate choices of conductor requirements for circuits less than 50 volts. Conductors for circuits less than 50 volts may be used if they:

- (a) meet the requirements of SAE J1127 "Battery Cable" or SAE J1128 "Low Tension Primary Cable" and the insulating material temperature rating requirements of SAE J378 "Marine Engine Wiring" such as those designated:

GPT, HDT, SGT, STS, HTS, and SXL, or
- (b) are classified as moisture resistant and flame retardant in Article 310 of the National Electrical Code, such as those designated:

THW, TW, THWN, XHHW, MTS, or
- (c) are flexible cords type SO, STO ST, SJO, SJT, SJTO, SE, SEO, SJ, SJEO, SJTOO, or STOO listed in Article 400 of the National Electrical Code (see Table 6), or
- (d) are conductors that meet the IEEE Standard 45, such as those designated:

R, B, T, V, AV, TA, M, S, or
- (e) are conductors that meet the requirements of UL Standard 1426.

Conductors for circuits of 50 volts or more must comply with 183.435

Conductors, as purchased, often do not indicate whether or not they conform with the above requirements and standards. If the conductors or their packaging are not so marked, then an alternate means of assurance of compliance should be obtained. Certification of compliance by the wire vendor is one acceptable means.

NOTE PERMITTED EXCEPTIONS 183.430(b)

TO COMPLY WITH THE LAW

- *All conductors for use in circuits of less than 50 volts meet 183.435, or,*
- *Meet the requirements of SAE J1127 or SAE J1128 and the insulating material temperature requirements of SAE Standard J378.*

FEDERAL LAW:**183.435 Conductors in Circuits of 50 Volts or More.**

- (a) Each conductor in a circuit that has a nominal voltage of 50 volts or more must be:
- (1) A conductor that has insulation listed and classified as moisture resistant and flame retardant in Article 310, NFPA No. 70, National Electric Code; or
 - (2) A flexible cord type SO, STO, ST, SJO, SJT, or SJTO listed in Article 400, NFPA No. 70, National Electric Code;
 - (3) A conductor that meets IEEE Standard 45;
 - (4) A conductor that meets UL Standard 1426.

This section applies only to wiring in circuits of 50 volts or more. However, conductors meeting any one of these alternate requirements will also qualify for circuits of less than 50 volts. The alternating current (AC) systems of 120 and 240 volts are the systems normally in use on boats to which these requirements apply.

Paragraphs (a)(1), (a)(3) and (a)(4) apply to conductors in general, while (a)(2) applies specifically to various types of flexible cords.

Types

Conductors for circuits of 50 volts or more may be used if they:

- (a) are classified as “moisture resistant” and “flame retardant” in Article 310 of the National Electrical Code, such as those designated:

THW, TW, THWN, XHHW, MTW or;

- (b) are flexible cords type SO, STO, ST, SJO, SJT, or SJTO, listed in Article 400 of the National Electrical Code, (see Table 6);

- (c) are conductors that meet the IEEE Standard 45, such as those designated:

R, B, T, V, AV, TA, M, S; or

- (d) are conductors that meet the requirements of UL Standard 1426.

There may be other cords or wires on the market, such as S, SE, SEO, SJE, SJE0, SJ00, SJTO0, and SOO, which have been accepted by the U.S. Coast Guard. If you are considering a cord or wire other than one listed above, check with the supplier for a copy of the Coast Guard's letter of acceptance.

Conductors, as purchased, often do not indicate whether or not they conform with the above requirements and standards. If the conductors or their packaging are not so marked, then an alternative means of assurance of compliance should be obtained. Certification of compliance by the cable vendor is one acceptable means.

Sizing

Table 5 is used to select the size of conductors. Correction factors are provided for conductors used in engine spaces (Note 1) and also for bundling of conductors used in circuits of 50 volts or more (Note 2).

Tables 5A through 5E have been developed for this guideline, and include corrected values, so it is not necessary to perform the calculations required if using Table 5. Select the proper table according to the number of 50 volts or more current carrying conductors in a bundle and then read the wire gauge needed according to the temperature rating, location of the conductor and the circuit lead. Refer to "How to Select a Conductor" which follows, for further information.

Conductors, as purchased, often do not display the temperature ratings of conductor insulation. If the conductors or their packaging are not so marked, then an alternate means of assurance of compliance should be obtained. Certification of compliance by a vendor is one acceptable means.

How to Select a Conductor

FACTORS

To select a conductor in accordance with the regulation, there are a number of factors to consider:

1. Temperature rating of conductor insulation.
2. Current rating required for the circuit.
3. Is the conductor in an engine space?
4. Is the system voltage less than 50 volts, or is it 50 volts or more?
5. How many conductors will run in a bundle?
6. What type of conductor is permitted; i.e. SAE, NEC, IEEE, UL or other?

PROCEDURE

1. Determine the circuit load — add up the rated loads of the electrical devices in the circuit.

The boat manufacturer will have to determine the circuit loads in the boat in order to properly size conductors and the related overcurrent protection. If a conductor is supplying a single load, sizing the conductor and its overcurrent protection is simple. If, however, a single conductor is supplying multiple or cumulative loads, such as a distribution panel, the boat manufacturer does not have to size the conductor to carry the summation of all the loads connected to the panel, but only a percentage of these loads, due to loading factors. The regulation does not require that a conductor be sized to carry the full load of a distribution panel, but does require that proper overcurrent protection be provided for the size of the conductor chosen.

The boat manufacturer has a choice between the extremes of providing a conductor that can carry the full load, and using a smaller conductor that is adequate because of load factors, but still large enough to avoid nuisance tripping of its overcurrent protection.

Of course, whichever size conductor is used, it must be protected with the proper size overcurrent protection. It must also be noted that 183.425(b) restricts the maximum load a conductor may carry to that specified in Table 5, except for intermittent higher currents. (See 183.455 and 183.460 for Overcurrent Protection Requirements).

2. Decide what temperature rating of conductor will be used.
3. If in an engine space, apply the correction factor to the amperage values in Table 5 for the temperature rating selected. Tables 5A through 5E provide a column of corrected amperages for use in engine spaces.
4. If the electrical system is 50 volts or more, determine the number of current carrying conductors (grounding conductors are not normally current carrying) that will be bundled together. If more than two, select the appropriate correction factor and apply it to the amperage values in Table 5 or as corrected for use in engine spaces. Tables 5B through 5E provide corrected amperages for various numbers of conductors in bundles and also provide a column for conductors used in engine spaces.
5. In Table 5 or Tables 5A through 5E under the column for the selected temperature rating of the conductor, find the amperage that, when the necessary correction factors are applied (not needed when using Tables 5A through 5E) equals or exceeds the circuit load.
6. Read the gauge of the conductor to be used.
7. Select a conductor of STRANDED COPPER construction with insulation properties permitted in accordance with the system voltage, as follows:
 - a) less than 50 volts — SAE conductors are permitted in addition to those for 50 volts and over. (See 183.430).
 - b) 50 volts or more — NEC, IEEE and UL conductors are permitted. (See 183.435).

EXAMPLES

1. A circuit in a boat consists only of a 12 volt bilge pump, rated at 12 amps. The bilge pump and its wiring are in the engine compartment and the conductors will run in a bundle of 8 conductors except where they break out of the bundle to go to the pump, a distance of 40 inches from the bundle.

FACTS

Circuit Load	12 amps
Location	Engine Space
Bundling	8 conductors
Voltage	Less than 50 volts

CONDUCTOR

The boat builder decides to use 75° C temperature rated conductors for the bilge pump.

ENGINE SPACE CORRECTION

The factor for 75° C conductors is 0.75.

CALCULATION

In Table 5, under 75° C, a 16 AWG conductor will carry 15 amps; however, when corrected for use in an engine space, it may only carry:

$$0.75 \times 15 = 11.25 \text{ amps} \quad \text{therefore 16 AWG conductors are too small.}$$

Try 14 AWG:

$$0.75 \times 20 = 15 \text{ amps} \quad 14 \text{ AWG, } 75^\circ \text{ C conductors may be used.}$$

Tables 5A through 5E may be used in lieu of these calculations.

NOTE:

Bundling corrections DO NOT apply to conductors used in circuits less than 50 volts.

2. A lighting and receptacle circuit is planned for the 120 volt AC system on a boat. The maximum permanent lighting load is known to be 5 amps. The receptacle load is unknown but the receptacles are rated at 15 amps. The conductors go through the engine space in a bundle of 8 conductors, 3 of which are DC and 5 of which are current carrying AC conductors.

FACTS

Circuit Load	Unknown
Location	Conductors run through engine space
Bundling	8 conductors; 3 DC, 5 AC
Voltage	50 volts or more (actually 120 volts AC).

CONDUCTOR

The boat builder decides to use 75° C temperature rated conductors for this lighting and receptacle circuit.

ENGINE SPACE CORRECTION

The factor for 75° C conductors is 0.75. The correction factor applies to the length of the conductors used in the engine space. The lengths outside the engine space need no correction. If a conductor runs inside and outside an engine space, it must be sized for the engine space.

CIRCUIT LOAD

Since the circuit load is unknown, the size of the circuit protection device will determine the anticipated load. In this case, 20 amps was selected.

CALCULATION

In Table 5, under 75° C, a 12 AWG conductor will carry 25 amps. Corrected for engine spaces it may only carry:

$$0.75 \times 25 = 18.75 \text{ amps} \quad 12 \text{ AWG, } 75^\circ \text{ C conductors are too small.}$$

Try 10 AWG

$$0.75 \times 40 = 30 \text{ amps}$$

Bundling Correction — Even though there are 8 conductors in the bundle, only 5 are current carrying in circuits of 50 volts or more. Therefore, the correction factor from Note 2 used is for bundles of 4 to 6 conductors, or 0.60.

Try 10 AWG, corrected for engine spaces:

$$0.60 \times 30 = 18 \text{ amps} \quad 10 \text{ AWG } 75^\circ \text{ C conductors are too small.}$$

Try 8 AWG

$$\begin{array}{ll} \text{Correct for engine spaces:} & 0.75 \times 40 = 30 \text{ amps} \\ \text{Correct for bundling:} & 0.60 \times 30 = 18 \text{ amps} \end{array}$$

8 AWG, 75° C conductors may be used in the engine spaces. Please note that outside the engine spaces, 10 AWG conductors may be used, as the following bundling calculation shows:

$$0.60 \times 40 = 24 \text{ amps}$$

Conductors with a higher insulation temperature rating could be used to reduce the size of the conductor. (Table 5C may be used in lieu of these calculations).

- For the same example used in (c)(2) above, there is another method for determining proper conductor size. Again, use a 20 ampere load and a 75° C rated conductor. This method avoids the iterative process used in examples (1) and (2). Simply divide the load, 20 amperes, by the correction factor for engine space:

CALCULATION

$$\frac{20}{0.75} = 26.67 \text{ amps}$$

Then divide the result (26.67 amperes) by the correction factor for bundling:

$$\frac{26.67}{0.60} = 44.44 \text{ amps}$$

Enter the 75° C column of Table 5 and select the first conductor size whose allowable amperage exceeds 44.44 amperes. In this case, a 10 AWG conductor is allowed to carry 40 amperes, which is not enough. An 8 AWG conductor can carry 65 amperes. The selection will have to be an 8 AWG conductor or larger. If an 80° C rating is used, then a 10 AWG conductor would be adequate. (Table 5C may be used in lieu of these calculations.)

TO COMPLY WITH THE LAW

- *All conductors used in circuits of 50 volts or more meet one or more of the acceptable alternatives of this section?*
- *All conductors used in circuits under 50 volts meet one or more of the acceptable alternatives of this section OR the requirements of 183.430?*

TABLE 6 Flexible Cords and Cables (from Article 400, NEC)

FEDERAL LAW:**183.435 Conductors in Circuits of 50 Volts or More.**

(b) Where the nominal circuit voltage of each of three or more current carrying conductors in a duct, bundle, or cable is 50 volts or more, the amperages of each of those conductors must not exceed the value in table 5 multiplied by the correction factor in Note 2 to Table 5 for the number of conductors that carry 50 volts or more.

To select the right bundling correction factor, count only the current carrying conductors that are in circuits of 50 volts or more. Other conductors in the same bundle do not have to be counted, such as grounding conductors, conductors from senders to gauges, and conductors in low voltage circuits less than 50 volts. For example, if a bundle contains a total of ten conductors:

3 — 12 volt system
1 — oil pressure gauge
2 — grounding conductors
4 — 120 volt AC system
10

then the bundling factor is based only on the 4 current carrying conductors in the 120 volt AC system.

Tables 5B through 5E contain tabulated values for allowable amperage in 50 volts and over circuitry in which 3 or more current carrying conductors are bundled. See the correct table for the bundling being selected: 5B = 3; 5C = 4 to 6; 5D = 7 to 24; and, 5E = 25 or more. These tables incorporate all necessary correction factors as noted in both 183.425 and 183.435. Also see sample calculations in the discussion of 183.435(a).

FEDERAL LAW:

183.435 Conductors in Circuits of 50 Volts or More.

- (c) This section does not apply to communication systems; electronic navigation equipment; resistance conductors that control circuit amperage; conductors in secondary circuits of ignition systems; and pigtails of less than seven inches of expose length.

FEDERAL LAW:**183.440 Secondary Circuits of Ignition Systems.**

- (a) Each conductor in a secondary circuit of an ignition system must meet SAE Standard J557.
- (b) The connection of each ignition conductor to a spark plug, coil, or distributor must have a tight fitting cap, boot, or nipple.

NOTE: SAE Standard 557 "High Tension Ignition Cable" is no longer sponsored by SAE and has been superseded by SAE J1191, "High Tension Ignition Cable Assemblies." It is expected that Title 33 CFR, Section 183.440 will be revised in the short future to reflect this change.

Conductors in secondary circuits of ignition systems consist of the conductor from the center tap on the ignition coil to the center or rotor terminal on the distributor cap and the spark plug wires. These conductors must meet the specialized requirements of SAE J557 "High Tension Ignition Cable". Both ends of these conductors must be connected in such a manner as to be protected by a tight fitting cap, boot or nipple. Caps, boots and nipples that meet test requirements incorporated in SAE J1191, "High Tension Ignition Cable Assemblies", are acceptable.

TO COMPLY WITH THE LAW

- Does each secondary circuit conductor meet the requirements of SAE Standard J557?
- Are all connected ends of secondary circuit conductors equipped with tight fitting caps, boots or nipples?

FIGURE 20 Ignition Conductor Connections

FEDERAL LAW:**183.445 Conductors: Protection.**

- (a) Each conductor or group of conductors that passes through a bulkhead, structural member, junction box, or other rigid surface must be protected from abrasion.

A conductor or bundle of conductors must have abrasion protection, in addition to its own insulation, where it goes through a hole. This applies to holes in any rigid surface such as a bulkhead, junction box, electric panel, etc. Any means such as clamping, grommets, caulking, hose, bushings, taping, special devices or others may be used. Note the requirements for isolation bulkhead openings in section 183.410(c), if applicable.

TO COMPLY WITH THE LAW

- *Is each conductor or bundle of conductors protected from chafe where it passes through a bulkhead, structural member, junction box or other rigid surface?*

FIGURE 21 Abrasion Protection

FEDERAL LAW:

183.445 Conductors: Protection.

- (b) Each ungrounded terminal or stud that is continuously energized must meet 183.455 or must have a boot, nipple, cap, cover, or shield that prevents accidental short-circuiting at the terminals or studs.

Any continuously energized terminal or stud that is not protected by a fuse or circuit breaker, as required by section 183.455, must be protected from accidental short circuiting. Continuously energized means directly connected to a power source without any switches or solenoids between the source and the terminal. Protection against accidental short circuiting must be by means of an insulated boot, nipple, or cap or by a cover or shield. The test to determine if the protection is effective is whether or not the terminal or stud can be touched by a 3/4 inch diameter ball. If it cannot be touched, then the protection is adequate.

TO COMPLY WITH THE LAW

Is each continuously energized terminal or stud protected by either:

- *overcurrent protection, as required in 183.455, or*
- *an insulated boot, nipple, cap, cover or shield?*

FIGURE 22 Terminal Protection

FEDERAL LAW:

183.455 Overcurrent Protection: General.

- (a) Each ungrounded current-carrying conductor must be protected by a manually reset, tripfree circuit breaker or fuse.

Each ungrounded conductor used to carry current must be protected by a fuse or a circuit breaker. If used, a circuit breaker must be of the manually reset type rather than the automatic reset type. Additionally, the circuit breaker must be of the tripfree type, which means that the breaker will open the circuit even if the handle is held in the "on" position.

TO COMPLY WITH THE LAW

Is each ungrounded current-carrying-conductor protected by:

- *a manually reset, tripfree circuit breaker, or a fuse?*

FIGURE 23 Overcurrent Protection

FIGURE 23 Overcurrent Protection (continued)

FIGURE 24 Overcurrent Protection Exceptions

FEDERAL LAW:**183.455 Overcurrent Protection: General.**

(b) A manually reset, tripfree circuit breaker or fuse must be placed at the source of power for each circuit or conductor except:

- (1) If it is physically impractical to place the circuit breaker or fuse at the source of power, it may be placed within seven inches of the source of power for each circuit or conductor, measured along the conductor.
- (2) If it is physically impractical to place the circuit breaker or fuse at or within seven inches of the source of power, it may be placed within 40 inches of the source of power for each circuit or conductor, measured along the conductor, if the conductor is contained throughout its entire distance between the source of power and the required circuit breaker or fuse in a sheath or enclosure such as a junction box, control box, or enclosed panel.

The circuit breaker or fuse required must be located in one of three places:

1. at the point where a conductor receives its power (see Figure 25a);
2. at the point where a smaller conductor is connected to a larger conductor (see Figure 25b); or
3. at the point where a circuit initially receives its power if the breaker or fuse is sized to protect the smallest conductor in the circuit. (See Figures 25c and 25d.)

The schematic in Figure 25e shows these three methods of overcurrent protection.

Locations 1 and 2 actually describe a single location. The point in a circuit where a smaller conductor is connected to a larger conductor becomes the source of power for the smaller conductor. Basically, each conductor, noting the permitted exceptions, must be provided with overcurrent protection. This overcurrent protection may be located at a conductor's power source or at the point where the circuit receives its power, as long as the current rating of the overcurrent protection device protects the smallest conductor. Circuits in which there is no reduction in conductor size must be protected at the circuit's source of power, again noting the permitted exceptions.

For shore power installations, the source of power is the dockside or shore located receptacle. The shore power cable and the main power feeders from the shore power inlet on the boat to the main distribution panel are protected by overcurrent protections at the dockside or shore locate connection.

Circuits using conductors of different insulation temperature ratings resulting in the use of smaller gauge conductor to carry the same or larger rated current must have overcurrent protection sized to protect the conductor with the lowest ampere rating. For example, if a 10 AWG supply conductor (60° C) is connected to a 14 AWG (125° C), the conductor ampere capacity is 40 amps in both cases and therefore one circuit breaker at the source end of the 10 AWG conductor is all that is needed.

TO COMPLY WITH THE LAW

Is there a manually reset, tripfree circuit breaker or fuse at the:

- *source of power for each conductor, or*
- *at the point where a smaller conductor is connected to a larger conductor, or*
- *at the origin of a circuit, providing it protects the smallest conductor in the circuit?*

FIGURE 25 Location of Overcurrent Protection

FIGURE 25 Location of Overcurrent Protection (continued)**NOTE:**

Up to 40" is allowed if the conductor, throughout this distance, is contained in a sheath or enclosure such as a junction box, control box, or enclosed panel.

FEDERAL LAW:**183.455 Overcurrent Protection: General**

(c) The current rating of each circuit breaker or fuse must not exceed:

- (1) For circuits of less than 50 volts, 150% of the value of the amperage in Table 5 for the conductor size it is protecting; and
- (2) For circuits of 50 volts or more, the value of the amperage in Table 5 for the conductor size it is protecting. If this value does not correspond to a standard size or rated circuit breaker or fuse the next larger size or rated circuit breaker or fuse may be used if it does not exceed 150% of the allowed current capacity of the conductor.

A circuit breaker or fuse must be sized so as not to exceed the permitted percentages of the current (ampere) rating of the conductor it is to protect as permitted in this section of the regulation. The current rating of the conductors must be taken from Table 5, including correction factors as applicable, as referred to in 183.425 and 183.435. The voltage of the circuit must be known in order to properly size the overcurrent protection.

(1) FOR LESS THAN 50 VOLTS

The breaker or fuse rating cannot exceed the Table 5 value by more than 150% (i.e. 1.5 times the table value). See Example A below.

(2) FOR 50 VOLTS OR MORE

The breaker or fuse should correspond exactly to the Table 5 value (See Example B). If, however, a standard rating of breaker or fuse does not correspond to the Table 5 value, then the next larger size breaker or fuse may be used, provided it does not exceed 150% (1.5 times) the Table 5 value (see Example C).

EXAMPLE A Less Than 50 Volts

For a No. 10 AWG 90° C conductor in an engine room, Table 5 gives a value of 45.1 amperes (55 X .82 correction factor). 150% of this value is 67.65 (45.1 X 1.5). The MAXIMUM breaker current rating would be 67.65 amperes. In practical terms, a 60 or 65 ampere device would be chosen.

EXAMPLE B 50 Volts or More

For a No. 6 AWG 105° C conductor in an engine room, Table 5 gives a value of 102 amperes (120 X .85 correction factor). If a standard size breaker or fuse is available in this rating, it should be used.

EXAMPLE C 50 Volts or More

For a No. 6 AWG 80° C conductor run with two other current carrying conductors, in circuits of 50 volts or more, in an engine room, Table 5 gives a value of 54.6 amperes (100 X .70 correction factor X .78 correction factor). As the next larger standard breaker or fuse rating is 60 amperes, this value may be used provided it does not exceed 150% of the table value. The 150% value would be 81.9 amperes (54.6 X 1.5) and, as 60 amperes is LESS than this, then a 60 ampere breaker or fuse is the maximum that may be used. Of course, a lower rated circuit breaker or fuse may be used, as could a larger conductor. The boat manufacturer will have to determine the circuit loads in the boat in order to properly size conductors and the related overcurrent protection. If a conductor is supplying a single load, sizing the conductor and its overcurrent protection is simple. If, however, a single conductor is supplying multiple or cumulative loads, such as a distribution panel, the boat manufacturer does not have to size the conductor to carry the summation of all the loads connected to the panel, but only a percentage of these loads, due to loading factors. The regulation does not require that a conductor be sized to carry the full load of a distribution panel, but does require that proper overcurrent protection be provided for the size of conductor chosen.

The boat manufacturer has a choice between the extremes of providing a conductor that can carry the full load, or, using a smaller conductor that is adequate because of load factors, but still large enough to avoid nuisance tripping of its overcurrent protection.

Of course, whichever size conductor is used, it must be protected with the proper size overcurrent protection. It must also be noted that 183.425(b) restricts the maximum load a conductor may carry to that specified in Table 5, except for intermittent higher currents as discussed under 183.425(b).

TO COMPLY WITH THE LAW

Is the current rating of each circuit breaker or fuse not in excess of:

- *150% of the amperage value in Table 5 for the conductor being protected in circuits less than 50 volts? or*
- *The amperage value in Table 5 for the conductor being protected in circuits of 50 volts or more, except if the Table 5 value is not a standard size circuit breaker or fuse, is it the next larger size but not in excess of 150% of the Table 5 value?*

FEDERAL LAW:**183.455 Overcurrent Protection: General.**

- (d) The voltage rating of each circuit breaker or fuse must not be less than the nominal circuit voltage of the circuit it is protecting.
- (e) This section does not apply to resistance conductors that control circuit amperages; conductors in secondary circuits of ignition systems; pigtails of less than seven inches of exposed length; and power supply conductors in cranking motor circuits.

In addition to a current (ampere) rating, a circuit breaker or fuse also has a voltage rating. A circuit breaker or fuse must have a voltage rating equal to, or preferably greater than, the nominal voltage of the circuit it is protecting. This is to ensure that the device will operate properly when an overcurrent (too many amperes) situation occurs. See Figure 26.

NOTE:

Nominal circuit voltage means the named voltage — i.e. a 12 volt DC system may charge at about 13.8 volts, but the nominal circuit voltage is 12 volts DC.

TO COMPLY WITH THE LAW

- *Is the voltage rating of each circuit breaker or fuse equal to, or higher than, the nominal circuit voltage of the circuit it is protecting?*

FIGURE 26 Voltage Rating of Overcurrent Protection

FEDERAL LAW:**183.460 Overcurrent Protection: Special Applications.**

- (a) Each ungrounded output conductor from a storage battery must have a manually reset, trip-free circuit breaker or fuse, unless the supply conductor is in the main power feed circuit from the battery to an engine cranking motor. The circuit breaker or fuse must be within 72 inches of the battery measured along the conductor, unless, for boats built prior to August 1, 1985, the circuit has a switch that disconnects the battery.

Ungrounded conductors connected to a storage battery, other than cranking motor conductors, must have overcurrent protection in accordance with 183.455(a). This section of the regulation provides an exception to 183.455(b) which allows the overcurrent protection location for the battery cable, as described, to be a distance from the connection at the battery (Section 182.455(b) requires the overcurrent protection to be at the power source). The distance from the battery connection depends on whether or not the overcurrent protection device is equipped with a switch.

- Overcurrent protection without a switch must be located within 72 inches of the battery connection. See Figure 25.
- Overcurrent protection with a switch may be located anywhere along the battery cable, if the boat was built before August 1, 1985. See Figure 25.

The only exception to the overcurrent protection requirement for conductors is for cranking motor power conductors, as excepted in 183.455(e). Schematics of typical main supply circuits are shown in Figure 25.

TO COMPLY WITH THE LAW

Except for the power supply conductors to the engine cranking motor:

- *Is there a manually reset, tripfree circuit breaker or fuse in each ungrounded output conductor from each storage battery?*
- *Is the circuit breaker or fuse within 72 inches of the battery, measured along the conductor? or*
- *If the boat was built prior to August 1, 1985, is there a switch in the circuit to disconnect the battery?*

FEDERAL LAW:**183.460 Overcurrent Protection: Special Applications.**

- (b) Each ungrounded output conductor from an alternator or generator, except for self-limiting alternators or generators, must have a circuit breaker or fuse that has a current rating that does not exceed 120 percent of the maximum rated current of the alternator or generator at 60° C.

The output of alternators or generators (AC or DC) must have overcurrent protection as described in 183.455. This must be by means of a circuit breaker or fuse rated at no more than 120% (1.2 times) of the maximum rated output current of the alternator or generator. As this output rating may be temperature sensitive, a 60° C (140° F) temperature is used as a standard (see Figure 27). The only exception to the breaker or fuse requirement is for “self limiting” alternators or generators. These are devices that are designed and manufactured to provide only a certain maximum output no matter how much load is applied (i.e. they cannot be overloaded). This information must be obtained from the alternator or generator manufacturer, or may be available on the nameplate.

NOTE:

Nameplates are good practice, but are not required by the regulation.

The “self limiting” concept can also be applied to certain battery chargers, magneto grounding circuits, and other similar components that provide electrical output for specific functions. This electrical output is limited by the construction of the electrical components no matter what the load, and when its output circuit is grounded, the voltage drops to zero.

The overcurrent protection requirements of section 183.455 apply to ungrounded conductors. For the purpose of these requirements, the conductors used with sender units such as fuel gauges, oil temperature switches, thermostats, etc., are considered to be grounded conductors and do not require overcurrent protection. The supply conductors to the gauge or other measuring systems are protected by overcurrent protection, and this indirectly protects the grounded conductors discussed above.

TO COMPLY WITH THE LAW

- *Is there a circuit breaker or fuse in each ungrounded output conductor from a non-self limiting alternator or generator?*
- *Is the circuit breaker or fuse rated at no more than 120% of the maximum rated current of the alternator or generator at 60° C?*

APPENDIX — References and Resources

The following standards are referenced in this regulation:

IEEE 45	"Electric Installations on Shipboard". Applies to section 183.435.
SAE J378	"Marine Engine Wiring". Within SAE J378, reference is made to ASTM D573, "Test for Rubber Deterioration in an Air Oven". Applies to section 183.430.
SAE J1127	"Battery Cable". Applies to 183.430.
SAE J1128	"Low Tension Primary Cable". Applies to section 183.440.

The following standards are referenced in this compliance guideline:

SAE J1171	"External Ignition Protection of Marine Electrical Devices". Applies to section 183.410.
SAE J1191	"High Tension Cable Assemblies". Applies to section 183.440.
UL 1426	"Cables for Boats".
UL 1500	"Standard Test Procedure for Ignition Protection".

SAE standards are available from the Society of Automotive Engineers, 400 Commonwealth Drive, Warrendale, PA 15096, (412) 776-4841.

UL (Underwriter Laboratories) standards are available from Underwriters Laboratories Marine Department, 12 Laboratory Drive, Research Triangle Park, NC 27709, (919) 549-1565.

U.S. Coast Guard regulations are available from the U.S. Government Printing Office, Superintendent of Documents, Washington, DC 20402-9328.
